

Deep Learning Basics Lecture 3: Regularization I

Princeton University COS 495

Instructor: Yingyu Liang

What is regularization?

- In general: any method to prevent overfitting or help the optimization
- Specifically: additional terms in the training optimization objective to prevent overfitting or help the optimization

Review: overfitting

Overfitting example: regression using polynomials

$$t = \sin(2\pi x) + \epsilon$$

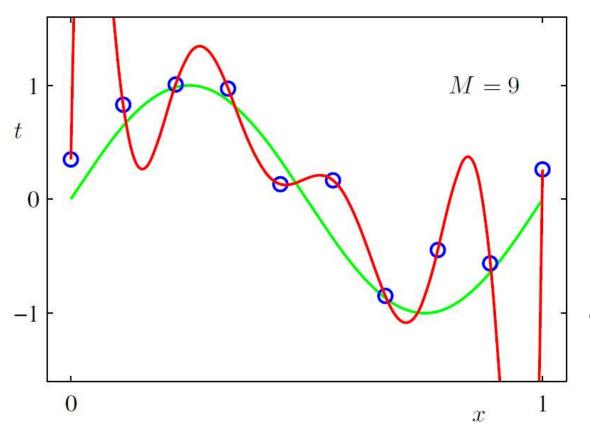

Figure from *Machine Learning* and *Pattern Recognition*, Bishop

Overfitting example: regression using polynomials

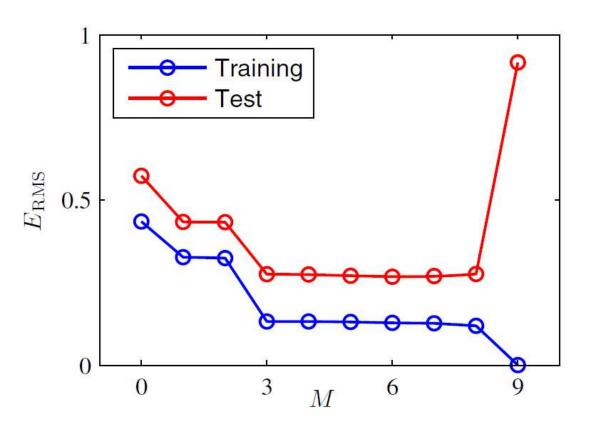

Figure from *Machine Learning* and *Pattern Recognition*, Bishop

Overfitting

- Empirical loss and expected loss are different
- Smaller the data set, larger the difference between the two
- Larger the hypothesis class, easier to find a hypothesis that fits the difference between the two
 - Thus has small training error but large test error (overfitting)

Prevent overfitting

- Larger data set helps
- Throwing away useless hypotheses also helps
- Classical regularization: some principal ways to constrain hypotheses
- Other types of regularization: data augmentation, early stopping, etc.

Different views of regularization

Regularization as hard constraint

Training objective

$$\min_{f} \hat{L}(f) = \frac{1}{n} \sum_{i=1}^{n} l(f, x_i, y_i)$$

subject to: $f \in \mathcal{H}$

When parametrized

$$\min_{\theta} \hat{L}(\theta) = \frac{1}{n} \sum_{i=1}^{n} l(\theta, x_i, y_i)$$

subject to: $\theta \in \Omega$

Regularization as hard constraint

• When Ω measured by some quantity R

$$\min_{\theta} \hat{L}(\theta) = \frac{1}{n} \sum_{i=1}^{n} l(\theta, x_i, y_i)$$

subject to: $R(\theta) \le r$

• Example: l_2 regularization

$$\min_{\theta} \hat{L}(\theta) = \frac{1}{n} \sum_{i=1}^{n} l(\theta, x_i, y_i)$$

subject to: $||\theta||_2^2 \le r^2$

Regularization as soft constraint

• The hard-constraint optimization is equivalent to soft-constraint

$$\min_{\theta} \ \widehat{L}_R(\theta) = \frac{1}{n} \sum_{i=1}^n l(\theta, x_i, y_i) + \lambda^* R(\theta)$$

for some regularization parameter $\lambda^* > 0$

• Example: l_2 regularization

$$\min_{\theta} \widehat{L}_R(\theta) = \frac{1}{n} \sum_{i=1}^n l(\theta, x_i, y_i) + \lambda^* ||\theta||_2^2$$

Regularization as soft constraint

Showed by Lagrangian multiplier method

$$\mathcal{L}(\theta, \lambda) \coloneqq \hat{L}(\theta) + \lambda [R(\theta) - r]$$

• Suppose θ^* is the optimal for hard-constraint optimization

$$\theta^* = \underset{\theta}{\operatorname{argmin}} \max_{\lambda \ge 0} \mathcal{L}(\theta, \lambda) \coloneqq \widehat{L}(\theta) + \lambda [R(\theta) - r]$$

• Suppose λ^* is the corresponding optimal for max

$$\theta^* = \underset{\theta}{\operatorname{argmin}} \mathcal{L}(\theta, \lambda^*) \coloneqq \widehat{L}(\theta) + \lambda^* [R(\theta) - r]$$

Regularization as Bayesian prior

- Bayesian view: everything is a distribution
- Prior over the hypotheses: $p(\theta)$
- Posterior over the hypotheses: $p(\theta \mid \{x_i, y_i\})$
- Likelihood: $p(\{x_i, y_i\}|\theta)$
- Bayesian rule:

$$p(\theta \mid \{x_i, y_i\}) = \frac{p(\theta)p(\{x_i, y_i\} \mid \theta)}{p(\{x_i, y_i\})}$$

Regularization as Bayesian prior

Bayesian rule:

$$p(\theta \mid \{x_i, y_i\}) = \frac{p(\theta)p(\{x_i, y_i\} \mid \theta)}{p(\{x_i, y_i\})}$$

Maximum A Posteriori (MAP):

$$\max_{\theta} \log p(\theta \mid \{x_i, y_i\}) = \max_{\theta} \log p(\theta) + \log p(\{x_i, y_i\} \mid \theta)$$
Regularization MLE loss

Regularization as Bayesian prior

• Example: l_2 loss with l_2 regularization

$$\min_{\theta} \hat{L}_{R}(\theta) = \frac{1}{n} \sum_{i=1}^{n} (f_{\theta}(x_{i}) - y_{i})^{2} + \lambda^{*} ||\theta||_{2}^{2}$$

• Correspond to a normal likelihood $p(x, y \mid \theta)$ and a normal prior $p(\theta)$

Three views

• Typical choice for optimization: soft-constraint

$$\min_{\theta} \hat{L}_R(\theta) = \hat{L}(\theta) + \lambda R(\theta)$$

• Hard constraint and Bayesian view: conceptual; or used for derivation

Three views

- Hard-constraint preferred if
 - Know the explicit bound $R(\theta) \leq r$
 - Soft-constraint causes trapped in a local minima with small heta
 - Projection back to feasible set leads to stability
- Bayesian view preferred if
 - Know the prior distribution

Some examples

Classical regularization

- Norm penalty
 - l_2 regularization
 - l_1 regularization

• Robustness to noise

l_2 regularization

$$\min_{\theta} \hat{L}_R(\theta) = \hat{L}(\theta) + \frac{\alpha}{2} ||\theta||_2^2$$

- Effect on (stochastic) gradient descent
- Effect on the optimal solution

Effect on gradient descent

Gradient of regularized objective

$$\nabla \hat{L}_R(\theta) = \nabla \hat{L}(\theta) + \alpha \theta$$

Gradient descent update

$$\theta \leftarrow \theta - \eta \nabla \hat{L}_R(\theta) = \theta - \eta \nabla \hat{L}(\theta) - \eta \alpha \theta = (1 - \eta \alpha)\theta - \eta \nabla \hat{L}(\theta)$$

Terminology: weight decay

• Consider a quadratic approximation around θ^*

$$\hat{L}(\theta) \approx \hat{L}(\theta^*) + (\theta - \theta^*)^T \nabla \hat{L}(\theta^*) + \frac{1}{2} (\theta - \theta^*)^T H(\theta - \theta^*)$$

• Since θ^* is optimal, $\nabla \hat{L}(\theta^*) = 0$

$$\widehat{L}(\theta) \approx \widehat{L}(\theta^*) + \frac{1}{2}(\theta - \theta^*)^T H(\theta - \theta^*)$$

$$\nabla \widehat{L}(\theta) \approx H(\theta - \theta^*)$$

Gradient of regularized objective

$$\nabla \hat{L}_R(\theta) \approx H(\theta - \theta^*) + \alpha \theta$$

• On the optimal θ_R^*

$$0 = \nabla \hat{L}_R(\theta_R^*) \approx H(\theta_R^* - \theta^*) + \alpha \theta_R^*$$
$$\theta_R^* \approx (H + \alpha I)^{-1} H \theta^*$$

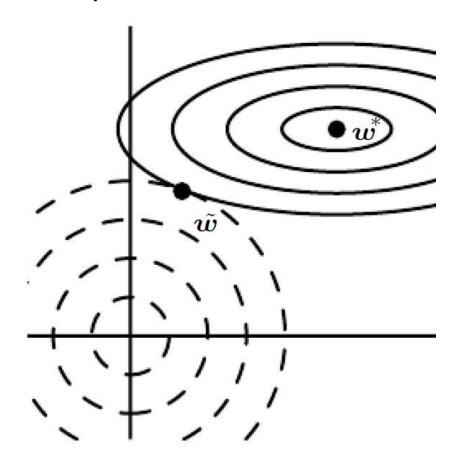

The optimal

$$\theta_R^* \approx (H + \alpha I)^{-1} H \theta^*$$

• Suppose H has eigen-decomposition $H = Q\Lambda Q^T$

$$\theta_R^* \approx (H + \alpha I)^{-1} H \theta^* = Q(\Lambda + \alpha I)^{-1} \Lambda Q^T \theta^*$$

Effect: rescale along eigenvectors of H

Notations:

$$\theta^* = w^*$$
, $\theta_R^* = \widetilde{w}$

Figure from *Deep Learning*, Goodfellow, Bengio and Courville

l_1 regularization

$$\min_{\theta} \ \hat{L}_R(\theta) = \hat{L}(\theta) + \alpha ||\theta||_1$$

- Effect on (stochastic) gradient descent
- Effect on the optimal solution

Effect on gradient descent

Gradient of regularized objective

$$\nabla \hat{L}_R(\theta) = \nabla \hat{L}(\theta) + \alpha \operatorname{sign}(\theta)$$

where sign applies to each element in θ

Gradient descent update

$$\theta \leftarrow \theta - \eta \nabla \hat{L}_R(\theta) = \theta - \eta \nabla \hat{L}(\theta) - \eta \alpha \operatorname{sign}(\theta)$$

• Consider a quadratic approximation around θ^*

$$\hat{L}(\theta) \approx \hat{L}(\theta^*) + (\theta - \theta^*)^T \nabla \hat{L}(\theta^*) + \frac{1}{2} (\theta - \theta^*)^T H(\theta - \theta^*)$$

• Since θ^* is optimal, $\nabla \hat{L}(\theta^*) = 0$

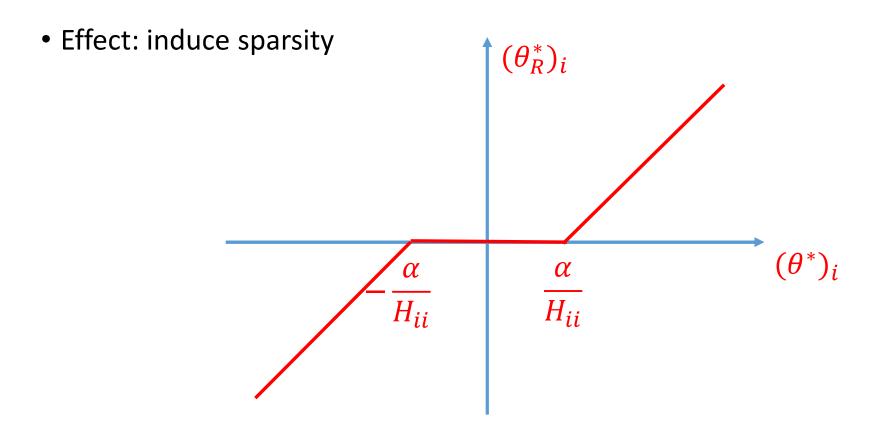

$$\hat{L}(\theta) \approx \hat{L}(\theta^*) + \frac{1}{2}(\theta - \theta^*)^T H(\theta - \theta^*)$$

- Further assume that H is diagonal and positive $(H_{ii} > 0, \forall i)$
 - not true in general but assume for getting some intuition
- The regularized objective is (ignoring constants)

$$\widehat{L}_R(\theta) \approx \sum_i \frac{1}{2} H_{ii} (\theta_i - \theta_i^*)^2 + \alpha |\theta_i|$$

• The optimal θ_R^*

$$(\theta_R^*)_i \approx \begin{cases} \max\left\{\theta_i^* - \frac{\alpha}{H_{ii}}, 0\right\} & \text{if } \theta_i^* \ge 0\\ \min\left\{\theta_i^* + \frac{\alpha}{H_{ii}}, 0\right\} & \text{if } \theta_i^* < 0 \end{cases}$$

- Further assume that H is diagonal
- Compact expression for the optimal θ_R^*

$$(\theta_R^*)_i \approx \operatorname{sign}(\theta_i^*) \max\{|\theta_i^*| - \frac{\alpha}{H_{ii}}, 0\}$$

Bayesian view

• l_1 regularization corresponds to Laplacian prior

$$p(\theta) \propto \exp(\alpha \sum_{i} |\theta_{i}|)$$

$$\log p(\theta) = \alpha \sum_{i} |\theta_{i}| + \text{constant} = \alpha ||\theta||_{1} + \text{constant}$$
